
In plain terms: "worst-group" is accuracy on the hard cases where the shortcut is missing — the true test of whether the model learned the disease rather than the tube/tag. JTT and DFR raise that bar over the plain baseline (ERM) with only a small cost to everyday accuracy (right-hand bars). The effect is far larger for the synthetic tag, because that shortcut was made deliberately strong and easy to unlearn; the real chest tube is a harder case.
